### 1 Riemannian Structure

**Definition 1.1** (Riemannian Structure). Let M be a smooth n-manifold. Then a **Riemannian Structure** on it is an assignment  $M \ni p \mapsto g_p$ , where  $g_p : T_pM \times T_pM \to \mathbb{R}$  is a bilinear, positive-definite, symmetric form, that depends smoothly on p. Such g is a **Riemannian metric**.

Specifically, if  $(x^1, \dots, x^n)$  is a coordinate system on  $U \subseteq M$ , then for  $i, j \in [1, n], p \in U$ , define

$$g_{ij}(p) = g_p \left( \frac{\partial}{\partial x^i} \Big|_p, \frac{\partial}{\partial x^j} \Big|_p \right)$$

where  $\frac{\partial}{\partial x^i}\Big|_p \in T_pM$  for all i. Then  $g_{ij}$  is  $C^{\infty}$ ; and  $g(p) = (g_{ij}(p))$  is a symmetric matrix that depends on p. The matrix is often referred to as the **metric tensor**. Evaluation on the metric can be done via  $g_p(v_1, v_2) = v_1^T g(p) v_2$ .

**Example 1.2.** Let  $M \subseteq \mathbb{R}^N$  be a smooth manifold. Then for all  $p \in M$ , via embedding the tangent space into  $\mathbb{R}^N$ ,  $T_pM \subseteq \mathbb{R}^N$ . The inner product in the usual sense (dot product in  $\mathbb{R}^n$ ) gives M a Riemannian structure. This implies that Euclidean Space obtains a Riemannian structure.

**Example 1.3.** Take  $M = S^2 \subset \mathbb{R}^3$ , and let  $U = S^2 \cap \{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid x_3 > 0\}$ . Specify the Riemannian structure as the inner product in  $\mathbb{R}^3$ , with the tangent space regarded as planes in  $\mathbb{R}^3$ , taking the local coordinate system as  $(x_1, x_2)$ , then at  $(x_1, x_2)$ , the metric tensor for the tangent space is given by

$$g = \frac{1}{1 - (x_1^2 + x_2^2)} \begin{pmatrix} 1 - x_2^2 & x_1 x_2 \\ x_1 x_2 & 1 - x_1^2 \end{pmatrix}$$

To see that this is indeed the metric, notice that at  $T_{(x_1,x_2)}M$ , the normal vector is given by  $(x_1,x_2,\sqrt{1-x_1^2-x_2^2})$ . Therefore  $\alpha\in T_{(x_1,x_2)}M$  must be in the form of  $(a,b,-\frac{ax_1+bx_2}{\sqrt{1-x_1^2-x_2^2}})$  for  $a,b\in\mathbb{R}$ . Let  $\boldsymbol{\beta}:=(c,d,-\frac{cx_1+dx_2}{\sqrt{1-x_1^2-x_2^2}})\in T_{(x_1,x_2)}M$ . Then

$$\langle \boldsymbol{\alpha}, \boldsymbol{\beta} \rangle = ac + bd + \frac{acx_1^2 + bdx^2 + (ad + bc)(x_1x_2)}{1 - x_1^2 - x_2^2}$$
$$= \frac{1}{1 - x_1^2 - x_2^2} \left( ac(1 - x_2^2) + bd(1 - x_1^2) + ad(x_1x_2) + bc(x_2x_1) \right)$$

where the entries of the metric tensor can be read off.

**Observation 1.4.** The <u>length</u> can thus be defined given the generalization of inner product on the structure. For  $\gamma:[0,1]\to M$ , the length of  $\gamma$ 

$$\|\gamma\| = \int_0^1 \sqrt{g_{\gamma(t)}\left(\frac{\mathrm{d}}{\mathrm{d}t}\gamma(t), \frac{\mathrm{d}}{\mathrm{d}t}\gamma(t)\right)} \mathrm{d}t =: \int_0^1 \sqrt{g_{\gamma(t)}\left(\dot{\gamma}, \dot{\gamma}\right)} \mathrm{d}t$$

If M is connected, Then the distance between  $a, b \in M$  is  $\inf_{\gamma(0)=a, \gamma(1)=b} \|\gamma\|$ .

### 2 Vector Bundle

**Definition 2.1** (Vector Bundle). A **(real) vector bundle of rank** k **over** M is a surjection  $\pi : \mathcal{E} \to M$  satisfying the following properties:

- 1. For all  $p \in M$ ,  $\mathcal{E}_p := \pi^{-1}(p)$  has a real vector space structure of dimension k.
- 2. For all  $p \in M$ , there exists an open neighborhood  $U \subset M$  containing p, and a diffeomorphism  $\chi : \pi^{-1}(U) \xrightarrow{\sim} U \times \mathbb{R}^n$  together with the projection  $p : U \times \mathbb{R}^n \to U$  s.t.
  - $\pi|_U=p\circ\chi$ , i.e. the following diagram commutes:

$$\pi^{-1}(U) \xrightarrow{\chi} U \times \mathbb{R}^n$$

$$\pi|_{\pi^{-1}(U)} \downarrow p$$

$$\downarrow U$$

• For all  $p \in U, \ \chi|_p : \mathcal{E}_p \to \{p\} \times \mathbb{R}^n$  is a linear isomorphism.

E is the total space, and M is the base. The map  $\chi$  is called the local trivialization of E at p.

#### **Example 2.2.** The following gives some examples of vector bundle:

- 1. The vector bundle which associates every point in M the vector space  $\mathbb{R}^n$ , given by  $\pi: M \times \mathbb{R}^n \to M$  is the trivial bundle.
- 2. Consider  $\mathcal{E} = TM$  which is the tangent bundle (or isomorphically, the cotangent bundle  $T^*M$ ), defined as  $TM = \coprod_{p \in M} T_p M$ . Then if  $\phi = (x^1, \dots, x^n)$  is a coordinate system on  $U \subset M$ , we have a basis  $\left\{\frac{\partial}{\partial x^1}, \dots, \frac{\partial}{\partial x^n}\right\}$  a basis of  $T_p M$  for each  $p \in M$ . The map  $\chi$  is then given by

$$\chi: \pi^{-1}(U) = TU \to U \times \mathbb{R}^n, \quad (p, T_pM \ni v) \mapsto (p, \langle v^1, \dots, v^n \rangle) \text{ s.t. } v = \sum_{i=1}^n v^i \frac{\partial}{\partial x^i}$$

 $\chi$  is a diffeomorphism as the tangent space TM has a smooth structure. Similarly one can consider the dual  $T^*M$  with basis  $\{dx^1, \ldots, dx^n\}$ . Then the corresponding map becomes

$$\chi: \pi^{-1}(U) = T^*U \to U \times \mathbb{R}^n, \quad (p, T_p^*M \ni \alpha) \mapsto (p, \langle a_1, \dots, a_n \rangle) \text{ s.t. } \alpha = \sum_{i=1}^n a_i \mathrm{d}x^i$$

where  $\alpha: T_pM \to \mathbb{R}$  is a linear map.

3. Let  $M \subset \mathbb{R}^N$  be a n-manifold. Define  $\mathcal{E} = \{(p,v) \mid p \in \mathcal{E}, v \in (T_pM)^\perp\}$ , The map can be defined as

$$\chi: \pi^{-1}(U) \to U \times \mathbb{R}^{N-n}, \quad (p, v) \mapsto (p, v)$$

which is the identity if one identifies  $T_pM$  with a subspace of  $\mathbb{R}^N$ .

**Definition 2.3** (Section). Let  $\pi: \mathcal{E} \to M$  be a vector bundle. Then a **(smooth) section** is a (smooth) map  $s: M \to \mathcal{E}$  s.t.  $\pi \circ s = \mathrm{Id}_M$ . The set of all smooth sections is denoted as  $\Gamma(\mathcal{E}, M)$ , or simply  $\Gamma(\mathcal{E})$ .

**Remark 2.4.** Explained in plain words, a section selects an element  $s(p) \in \mathcal{E}_p$  for each  $p \in M$ . Let  $\mathcal{E} = TM$ , and identifying the tangent space with  $\mathbb{R}^N$  for some N, then a section s gives a vector field on M.

Remark 2.5.  $\Gamma(\mathcal{E})$  defines a module structure over  $C^{\infty}(M)$ , with the scalar multiplication defined as  $\chi(f \cdot s(x)) = (x, f(x) \cdot (p_r \circ \chi \circ s)(x))$ , where  $p_r : (U, \mathbb{R}^n) \to \mathbb{R}^n$  is the projection that takes the second field. This map is smooth, as both  $f, p_r, \chi$  and s are smooth.

**Definition 2.6** (Moving Frame). Let  $\mathcal{E} \to M$  be a vector bundle, and  $U \subset M$  an open set. Then a **moving frame** of  $\mathcal{E}$  on U is an r-tuple  $(E_1, \ldots, E_r)$  s.t. for all  $j, E_j$  is a section of  $\mathcal{E} \supset \pi^{-1}(U) \to U$ ; and for all  $p \in U, (E_1(p), \ldots, E_r(p))$  gives a basis of  $\mathcal{E}_p$ .

**Remark 2.7.** There is a bijection between moving frames of  $\mathcal E$  on U and trivializations  $\chi:\pi^{-1}(U)\to U\times\mathbb R^n$ :

• Given a moving frame  $(E_1, \ldots, E_r)$  of  $\mathcal{E}$  on U, define

$$\chi: \pi^{-1}(U) \to U \times \mathbb{R}^n, \quad v \mapsto (\pi(v), \langle v^1, \dots, v^n \rangle) \text{ s.t. } v = \sum_{i=1}^n v^i E_i(p)$$

• Conversely, given a trivialization  $\chi: \pi^{-1}(U) \to U \times \mathbb{R}^n$ , define

$$E_i: M \supset U \to \pi^{-1}U \subset \mathcal{E}, \quad p \mapsto \chi^{-1}(p, \langle 0, \dots, 0, 1, 0, \dots, n \rangle)$$
i-th position

The vector space structure is induced by the vector space structure of  $\mathbb{R}^n$ .

**Definition 2.8** (Transition). Let  $\pi: \mathcal{E} \to M$  be a vector bundle, and  $U_{\alpha}, U_{\beta} \subset M$  two open subsets of M, and  $\chi_{\alpha}, \chi_{\beta}$  be the corresponding local trivializations. Define  $\phi_{\alpha,p} := p_r \circ \chi_{\alpha}$  where  $p_r: (U, \mathbb{R}^n) \to \mathbb{R}^n$  is the projection. Then the **transition** between  $\chi_{\alpha}$  and  $\chi_{\beta}$  is a map  $\tau_{\alpha\beta}$  s.t. for  $f_{\alpha\beta}: U \times \mathbb{R}^n \to U \times \mathbb{R}^n, (p,v) \mapsto (p,\tau_{\alpha\beta}(v))$ , the following diagram commutes:

$$\pi^{-1}(U_{\alpha} \cap U_{\beta}) \xrightarrow{\chi_{\alpha}} (U_{\alpha} \cap U_{\beta}) \times \mathbb{R}^{r}$$

$$\downarrow^{f_{\alpha\beta}}$$

$$(U_{\alpha} \cap U_{\beta}) \times \mathbb{R}^{r}$$

**Observation 2.9.**  $\tau_{\alpha\beta}:U_{\alpha}\cap U_{\beta}\to \mathrm{GL}_r(\mathbb{R})$ . It is smooth as  $\chi$  is a diffeomorphism.

**Remark 2.10.** By definition it is clear that  $\tau_{\alpha\beta}=\tau_{\beta\alpha}^{-1}$ ; and  $\tau_{\alpha\beta}\circ\tau_{\beta\gamma}=\tau_{\alpha\gamma}$ .

**Observation 2.11.** By the fact that any object defined on the vector space can be transferred to the vector bundle via the local trivialization since it is a diffeomorphism, constructions on vector spaces can be identified with constructions on vector bundles.

**Lemma 2.12** (Bundle Chart Lemma). Given M a smooth manifold, and for all  $p \in M$  associate an r-dimensional vector space  $\mathcal{E}_p$  to it. Define  $\mathcal{E} := \coprod_{p \in M} \mathcal{E}_p$ , and  $\pi : \mathcal{E} \to M, (p, v) \mapsto p$ . Further the followings are satisfied:

- There exists an open cover  $\{U_{\alpha}\}$  of M.
- For all  $\alpha$ , there exists a bijective map  $\chi_{\alpha}: \pi^{-1}(U_{\alpha}) \xrightarrow{\sim} U_{\alpha} \times \mathbb{R}^{n}$  s.t.  $\pi = p \circ \chi_{\alpha}$  where p is the projection  $U_{\alpha} \times \mathbb{R}^{n} \to U_{\alpha}$ .

Then there exists a unique  $C^{\infty}$  manifold structure on  $\mathcal E$  s.t.  $\chi_{\alpha}$  is a diffeomorphism; and  $\mathcal E$  is a  $C^{\infty}$  bundle over M.

The proof of the lemma is via verifying that  $\mathcal{E}$  is indeed a manifold, and is omitted here. The more interesting aspect is that this provides a lot of operations on bundles, for example combination of two bundles:

**Example 2.13.** Let  $(U_{\alpha})$  be an open cover of M, and  $\pi': \mathcal{E}' \to M$ ,  $\pi'': \mathcal{E}'' \to M$  be two vector bundles over M. Define  $\mathcal{E}' \oplus \mathcal{E}'' \to M$ , where  $\mathcal{E}' \oplus \mathcal{E}'' = \coprod_{p \in M} (\mathcal{E}'_p \oplus \mathcal{E}''_p)$ , Let  $(U_{\alpha})$  be a cover of M s.t. both  $\mathcal{E}'$  and  $\mathcal{E}''$  trivialize over each  $U_{\alpha}$ . Then it is valid to define the trivialization  $\chi: \pi^{-1}(U_{\alpha}) \to U_{\alpha} \times (\mathbb{R}^{r'} \oplus \mathbb{R}^{r''})$  s.t.  $\phi_{\alpha,p} = \phi'_{\alpha,p} \oplus \phi''_{\alpha,p}$ . In matrices this gives a block diagonal matrix.

### 3 Tensors

**Definition 3.1** (Free Vector Space). Let S be a (possibly infinite) set, and K a field. The **free vector space** generated by S over K is defined as the set

$$FS := \left\{ \sum_{s \in S} \alpha_s s \mid \text{finite nonzero } \alpha_s \right\}$$

satisfying the axioms of vector spaces, i.e. linear in s with addition and scalar multiplication.

**Definition 3.2** (Tensor Product). Let V, W be finite dimensional vector space. The **tensor product of** V **and** W, denoted  $V \otimes W$  is the free vector space generated by  $(V \times W)/\sim$ , where  $\sim$  follows the rules:

- $(v+v',w) \sim (v,w) + (v',w)$  for  $v,v' \in V, w \in W$ .
- $(v, w + w') \sim (v, w) + (v, w')$  for  $v \in V, w, w' \in W$ .
- $(cv, w) \sim c(v, w) \sim (v, cw)$  for  $c \in K, v \in V, w \in W$ .

This gives a map  $\otimes : V \times W \to V \otimes W$ ,  $(v, w) \mapsto [(v, w)]$  which is an equivalence class in  $V \otimes W$ .

**Proposition 3.3** (Universal Property of Tensor Product). Let Z be a real vector space, and the map  $b: V \times W \to Z$  bilinear. Then there exists a unique linear map  $f: V \otimes W \to Z$  s.t. the following diagram commute:

$$V\times W \xrightarrow{\otimes} V\otimes W$$

**Corollary 3.4.** Let  $(v_i)$  be a basis of V, and  $(w_i)$  a basis of W. Then  $(v_i \otimes w_j)$  gives a basis of  $V \otimes W$ , with  $\dim V \otimes W = \dim V \cdot \dim W$ .

Remark 3.5. Not every element in  $V \otimes W$  can be expressed as  $v \otimes w$  for some  $v \in V, w \in W$ . In particular, one can have  $v' = \sum_{i \in I} v_i \otimes w_i \in V \otimes W$ , whose representative cannot be further simplified.

**Proposition 3.6.** Let V and W be finite dimensional real vector space. Then there exists a natural isomorphism  $V \otimes W \stackrel{\sim}{\longrightarrow} \operatorname{Hom}(V^*,W)$ . In particular, this gives  $V^* \otimes V^* \simeq \operatorname{Hom}(V,V^*) \simeq \{\text{bilinear forms } V \times V \to \mathbb{R}\}.$ 

*Proof.* To construct the map it suffices to give a bilinear map  $V \times W \to \operatorname{Hom}(V^*, W)$ . Define it as

$$(v, w) \mapsto (\alpha \mapsto \alpha(v)w) \in \operatorname{Hom}(V^*, W)$$

Applying the universal property gives the desired result.

Remark 3.7. This can be extended to multiple tensor products:

$$\underbrace{V \otimes \cdots \otimes V}_{k} \otimes \underbrace{V^{*} \otimes \cdots \otimes V^{*}}_{\ell} \quad \simeq \quad \underbrace{(V^{*} \times \cdots \times V^{*}}_{k} \times \underbrace{V \times \cdots \times V}_{\ell} \to \mathbb{R})$$

where RHS is a multilinear map.

Definition 3.8 (Tensor). Denote

$$G = \underbrace{V \otimes \cdots \otimes V}_{k} \otimes \underbrace{V^* \otimes \cdots \otimes V^*}_{\ell}$$

Then an element in G is called a  $(k, \ell)$ -tensor on V. k is the contravariant degree, and  $\ell$  is the covariant degree.

**Remark 3.9.** It is possible to define the tensor product of maps. Namely, for  $f:V\to V'$  and  $g:W\to W'$ , there exists a unique linear map  $f\otimes g:V\otimes W\to V'\otimes W'$  s.t.  $(f\otimes g)(v\otimes w)=(f(v))\otimes (g(w))$ . This can be seen via consider first the  $\mathbb{R}$ -balanced linear map  $V\times W\to V\otimes W$ ; and apply the universal property of tensor product gives the desired result.

**Observation 3.10.** Similar to Example 2.13 where we considered the direct sum of vector bundles as a new bundle, we can consider the tensor product of vector bundles. For  $\mathcal{E}'$  and  $\mathcal{E}''$  two vector bundles,  $\coprod_{p\in M} \mathcal{E}'_p \otimes \mathcal{E}''_p$  gives a vector bundle structure over M. In particular, this can be extended to the tangent and cotangent spaces of a manifold.

**Notation.** Given a smooth manifold M, for  $k, \ell \in \mathbb{Z}_{>0}$ , denote

$$\mathscr{T}^{(k,\ell)}M=\Pi^{(k,\ell)}M=\underbrace{TM\otimes\cdots\otimes TM}_{k}\otimes\underbrace{T^{*}M\otimes\cdots\otimes T^{*}M}_{\ell}$$

In particular, this is TM for  $k=1, \ell=0$ , and is  $T^*M$  for  $k=0, \ell=1$ . By identification in Remark 3.7 maps  $\Pi^{(k,\ell)}M \to M$  are always multilinear (with the identification with the Euclidean Space).

**Definition 3.11** (Tensor Field). Let M be a smooth manifold. A  $(k, \ell)$ -tensor (field) on M is a smooth section of  $\Pi^{(k,\ell)}M$ .

In local coordinates, if we have local coordinates  $(x^1, \dots, x^n)$  on  $U \subseteq M$ , then any element in  $\Pi^{(k,\ell)}M$  is in the form of

$$f_{j_1,\dots,j_\ell}^{i_1,\dots,i_k} := \frac{\partial}{\partial x^{i_1}} \otimes \dots \otimes \frac{\partial}{\partial x^{i_k}} \otimes \mathrm{d} x^{j_1} \otimes \dots \otimes \mathrm{d} x^{j\ell}$$

where  $i_k$ s and  $j_\ell$ s run over  $\{1,\ldots,n\}$  arbitrarily. A section on  $\Pi^{(k,\ell)}M$  is then  $\sum_{i,j} f^{i_1,\ldots,i_k}_{j_1,\ldots,j_\ell}$ , with it being smooth implies that all such fs are smooth (as functions).

### 4 Riemannian Metric

**Definition 4.1** (Riemannian Metric). Given a Riemannian manifold M, a **Riemannian Metric** on M is a (0, 2)-tensor g that is symmetric and positive definite. In local coordinates,

$$g = \sum_{i,j=1}^{n} g_{ij} \mathrm{d}x^{i} \otimes \mathrm{d}x^{j}$$

That is, for all  $p \in M$ ,  $g_p : T_pM \times T_pM \to \mathbb{R}$  is bilinaer and symmetric; and for all  $v \in T_pM$ ,  $g_p(v,v) \ge 0$ , with equality reached if and only if v = 0.

**Observation 4.2.** Notice that in local coordinates we have  $v=v^i\frac{\partial}{\partial x^i}$ ,  $w=w^j\frac{\partial}{\partial x^j}$ . Evaluating the metric gives

$$(\mathrm{d}x^i \otimes \mathrm{d}x^j)(v,w) = v^i w^j = v^j w^i = (\mathrm{d}x^i \otimes \mathrm{d}x^j)(w,v) \implies q_{ij} = q_{ij}$$

Therefore, we can write

$$g = \frac{1}{2} (g_{ij} dx^{i} \otimes dx^{j} + g_{ji} dx^{j} \otimes dx^{i}) = \frac{1}{2} g_{ij} (dx^{i} \otimes dx^{j} + dx^{j} \otimes dx^{i})$$
$$= g_{ij} (\frac{1}{2} (dx^{i} \otimes dx^{j} + dx^{j} \otimes dx^{i}))$$

where  $(dx^i \otimes dx^j + dx^j \otimes dx^i) \in Sym(T_pM)$  which is in the symmetric tensor, i.e. invariant w.r.t permutation of the entries.

**Definition 4.3** (Riemannian Manifold). A **Riemannian Manifold** is a pair (M, g) where g is a Riemannian metric on M.

**Definition 4.4** (Isometry). A  $C^{\infty}$ -map  $F:(M_1,g_1)\to (M_2,g_2)$  is an **isometry** if and only if

- 1) F is a diffeomorphism.
- 2) For all  $p \in M_1$ ,  $u, v \in T_pM_1$ ,  $g_2(d_pF(u), d_pF(v)) = g_1(u, v)$ .

F is a **local isometry** if only 2) holds.

**Remark** 4.5. Since g is nondegenerate,  $d_pF$  is bijective as otherwise LHS of the equality in 2) will vanish. This then implies that  $\dim M_1 = \dim M_2$ , otherwise  $d_pF$  will either be not injective  $(\dim M_1 > \dim M_2)$  or not surjective  $(\dim M_1 < \dim M_2)$ .

**Theorem 4.6.** Any  $C^{\infty}$ -manifold M has a Riemannian metric.

*Proof.* Let  $\{(U_{\alpha}, \varphi_{\alpha})\}$  be an atlas of M. By definition of the chart we have the embedding  $\varphi_{\alpha}(U_{\alpha}) \longrightarrow \mathbb{R}^{n}$ . Define in  $U_{\alpha}$  the metric s.t.  $\varphi_{\alpha}$  is an isometry. In local coordinates, the metric can be expressed as  $g_{\alpha} = \sum_{i} dx_{\alpha}^{i} \otimes dx_{\alpha}^{j}$ .

Let  $(\chi_{\alpha})$  be a partition of unit subordinated to  $(U_{\alpha})$  and  $g = \sum_{\alpha} \chi_{\alpha} g_{\alpha}$ . Nondegeneracy of the metric g follows from the positivity of metric  $g_{\alpha}$  and  $\chi_{\alpha}$ .

**Example 4.7.** The following gives two constructions of Riemannian Metrics:

- 1) Let (M,g) be a Riemannian manifold, with  $N\subset M$  a submanifold. Then N inherits a Riemannian metric from the Riemannian structure on M, as for all  $p\in N, T_pN\subset T_pM$ .
- 2) Consider Cartesian product of Riemannian manifolds. Given two Riemannian manifolds  $(M_1, g_1)$ ,  $(M_2, g_2)$ , consider  $M_1 \times M_2$ . Then for all  $(p_1, p_2) \in M_1 \times M_2$  we have the identification between the tangent spaces

$$T_{(p_1,p_2)}(M_1 \times M_2) \simeq T_{p_1} M_1 \oplus T_{p_2} M_2$$

Then in coordinates, the combined metric is block diagonal:

$$g = \begin{pmatrix} g_1 & 0 \\ \hline 0 & g_2 \end{pmatrix}$$

### 5 Coverings

**Definition 5.1** (Covering). A  $C^{\infty}$  surjective map  $\pi: M \to N$  is a  $C^{\infty}$ -covering if for all  $q \in N$ , there exists U, a connected neighborhood of q s.t. if  $\pi^{-1}(U) = \coprod_j V_j$ , where  $V_j$  are connected components of  $\pi^{-1}(U)$ ; and for all j,  $\pi|_{V_j}: V_j \to U$  is a diffeomorphism.

Definition 5.2 (Automorphism of Covering). The automorphism on the covering is defined as

$$\operatorname{Aut}(\pi) := \{F : M \to M \text{ diffeomorphisms } | \pi \circ F = \pi\}$$

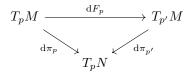

For any  $f \in Aut(\pi)$ , it shuffles the fibers  $\{\pi^{-1}(q) \mid q \in N\}$ .

**Definition 5.3** (Normal Covering). A covering  $\pi$  is **normal** if  $\operatorname{Aut}(\pi)$  acts transitively on fibers.

**Proposition 5.4.** Suppose that we have a manifold M has a Riemannian metric,  $\pi:M\to N$  is a covering. If for all  $f\in \operatorname{Aut}(\pi)$  it is an isometry, then there exists a unique Riemannian metric on N s.t.  $\pi$  is a local isometry.

*Proof.* Fix  $q \in N$ . Choose  $p \in \pi^{-1}(q)$ . Since  $\pi$  restricted to a neighborhood of p is a diffeomorphism, the differential  $d\pi_p : T_pM \to T_qN$  is bijective. Define the metric on  $T_qN$  s.t.  $d\pi_p$  is a linear isometry.

Check that this is compatible with the covering: if we have another choice  $p' \in \pi^{-1}(q)$ , by assumption there exists  $F \in \operatorname{Aut}(\pi)$  an isometry s.t. F(p) = F(p'); and  $\mathrm{d}F_p : T_pM \to T_{p'}M$  is a linear isometry. Then the composition is also a linear isometry:

**Example 5.5.** The following gives some simple examples of coverings:

- The covering  $\pi: S^n \to \mathbb{RP}^n$ , where the antipodal points are identified. Aut $(\pi)$  is the antipodal map.
- Let  $\Lambda \subset \mathbb{R}^n$  be a lattice (e.g.  $\Lambda = \mathbb{Z}^n$ ). Considering  $\mathbb{R}^n \to \mathbb{R}^n/\Lambda$  gives a covering map.  $\operatorname{Aut}(\pi)$  are translations by  $\Lambda$ .
- The hyperbolic space. Let M be the upper half plane  $\mathbb{H} = \{(x,y) \mid y > 0\}$  with metric  $\mathrm{d}s^2 = \frac{1}{y^2}(\mathrm{d}x^2 + \mathrm{d}y^2)$ . It turns out that any compact surface of genus > 1 is covered by  $\mathbb{H}$ . The covering  $\pi : \mathbb{H} \to S$  is such that  $\mathrm{Aut}(\pi)$  acts by isometries; and the metrics on S is locally isometric to the hyperbolic metric.

# 6 Metric on Lie Group

# 7 Common Objects on Riemannian Manifolds
